Get Connected coverage implementation workshare

Prepared for Galaxy Digital / Get Connected client solutions
TokenJunkieLabs · 11 October 2026

A complete coordinator workflow around the existing Get Connected site: original source capture, explicit rules, explainable coverage decisions, corrected inputs and repeatable handover.

The operating problem

Volunteer responses, qualification dates, team reservations and changing availability need to stay connected through each staffing decision. Your current API guidance assigns external integration implementation to client subject matter experts. We can supply that engineering capacity and the completed operating application.

What the workshare delivers

Source and policy	Actual CSV/JSON field mappings or selected Get Connected reads; original request/response bytes and IDs; coordinator-owned availability, eligibility, weekly caps, qualification requirements and extra reserved places.
Coverage review	The original ShiftLoom planner checks full-shift qualification validity, committed overlaps and workload before proposing complete coverage for a selected shift. Each candidate retains its original source-linked reason.
Corrections	Named approval, rejection and reversal; current-source checks; corrected exports and fresh scenarios beside prior review history. Earlier source versions remain intact.
Operating handover	Complete application source, configured mappings, coordinator guide, reviewed roster/change export, original-source handoff and full SQLite backup that reopens in a new process.

USD 6,400 · 10 business days · 50/50 payment

One Get Connected site and one agreed source/report family; up to 250 volunteers, 100 shifts and 5,000 coordinator availability/eligibility rows. Includes the first seven-day planning cohort, its committed assignment context, two corrected source iterations and operator handover.

USD 3,200 at the agreed start; USD 3,200 on delivery and handover. The schedule starts after the agreed source sample or authorized API access, actual policy inputs and a designated coordinator are available.

Delivery and adoption

Complete source-to-coordinator operation, with retained correction history.

Days 1–2	Confirm the actual source family, selected cohort, original identifiers/statuses, reserved places and named coordinator inputs. Configure capture or report intake.
Days 3–5	Finish field/status mappings and coordinator rules. Run the first actual cohort through candidate review and a named source-current decision.
Days 6–8	Process the two corrected source iterations, retain prior decisions, resolve the agreed mapping issues and produce the reviewed handoff.
Days 9–10	Reopen the complete backup on the agreed operator runtime. Transfer the source/configuration and walk the coordinator through repeat operation and recovery.

Acceptance

The coordinator can inspect the agreed original inputs and mappings, account for named and reserved places, review actual candidate eligibility and conflicts, record a named current-source decision, process the corrected exports and reopen the retained workspace from its backup.

Roles and runtime

Galaxy Digital or the client retains the customer relationship, source-access authority and scheduling/eligibility policy. TokenJunkieLabs supplies implementation, configuration and handover. Get Connected remains the system of record; the coordinator enters approved changes through the existing site workflow.

The runtime uses Python 3.10+, Node 22.16+ and the site’s IANA time-zone data on the agreed local computer or customer-managed Linux environment. Additional sites, source systems or a materially larger cohort can be priced once the actual source is visible.

Working product

The supplied worked cohort carries ten volunteers and three shifts through an original approval, reversal, changed availability and renewed qualification, with the corrected decision retained beside its predecessor. The customer implementation uses the same workflow with the agreed organization’s actual source and coordinator inputs.
