Stellar merchant close with Bitwave Data Fusion

Bring merchant payment context and reviewed book references into a complete, retained close workflow.

$5,600 fixed · eight business days

$2,800 at kickoff · $2,800 at acceptance

Delivery begins after the agreed source populations, authorized customer access, schema decisions and reviewers are available.

The engagement

One agreed merchant report family, one customer organization and approved Data Fusion schema; up to **5,000 source events across two monthly closes**; and up to **two corrected accountant returns**. Each close has a labeled plan tied to its original report or saved period snapshot.

Source and mapping	Configure the customer export into the original accountant handoff. Retain source identity, asset/unit labels, exact native amounts, network and payment context.
Data Fusion delivery	Prepare the approved data-source schema and native request batches. Retain delivery results and complete returned row pages for the selected organization.
Review and correction	Match returned rows to original events. Resolve missing, changed and duplicate source rows; preview and save the accountant’s external references, account codes, statuses and notes.
Working handoff	Transfer runnable source, configuration, original-source close packets, correction history and operator instructions. Reopen the backed-up environment with the recipient.

Source-preserved operation

The existing merchant accountant engine owns handoffs and returned assignments. Original amounts, assets and network labels remain attached to each event. The designated accountant selects the bookkeeping interpretation, account mapping and final close decisions.

An operable close, transferred

Days 1–2	Confirm the two close populations and owners. Configure source mapping, exact units, the approved Data Fusion schema and destination naming.
Days 3–4	Deliver the first close to the authorized customer destination, retain native results, capture the complete returned rows and resolve source differences.
Days 5–6	Preview and retain the accountant’s return; complete the agreed corrections. Repeat the operation for the second close, preserving both histories.
Days 7–8	Resolve acceptance items, transfer the working source and configuration, walk through correction/history views and perform backup/reopen with the recipient.

Inputs and named ownership

Provide the representative report/export family, two close populations, source field definitions and units, the selected Bitwave organization and authorized API access, schema preferences, a technical owner and a designated accountant. The source owner confirms event coverage; the accountant supplies the external-account mapping, references and review decisions.

Acceptance with the customer

1. Both close populations trace to their original records with exact amount and network fields.
2. Configuration, native requests/results and complete captured rows are retained and inspectable.
3. Source differences are resolved or assigned, and matched rows pass through the original accountant preview and save.
4. Current and prior returns reopen with the approved bookkeeping references and history.
5. The recipient receives runnable source and instructions and reopens the backed-up workspace.

Scope and operation

The fixed engagement includes source configuration, both close populations, two corrected return cycles and complete operator transfer. Additional report families, organizations, periods, ERP interfaces or an ongoing monthly service can be scoped from the actual workload.
